Facial Nerve Palsy

Synonym: Bell's palsy (lower motor neurone facial palsy); idiopathic facial paralysis (IFP)

Damage to the facial nerve - either upper motor neurone (UMN) or lower motor neurone (LMN) - produces weak muscles of facial expression.

Neuroanatomy[1]

The VIIth cranial (facial) nerve is largely motor in function (some sensory fibres from external acoustic meatus, fibres controlling salivation and taste fibres from the anterior tongue in the chorda tympani branch). It also supplies the stapedius (so a complete nerve lesion will alter auditory acuity on the affected side). From the facial nerve nucleus in the brainstem, fibres loop around the VI nucleus before leaving the pons medial to VIII and passing through the internal acoustic meatus. It passes through the petrous temporal bone in the facial canal, widens to form the geniculate ganglion (taste and salivation) on the medial side of the middle ear, whence it turns sharply (and the chorda tympani leaves), to emerge through the stylomastoid foramen to supply all the muscles of facial expression, including the platysma.

Presentation

Weakness of the muscles of facial expression and eye closure. The face sags and is drawn across to the opposite side on smiling. Voluntary eye closure may not be possible and can produce damage to the conjunctiva and cornea.

- In partial paralysis, the lower face is generally more affected.
- In severe cases, there is often demonstrable loss of taste over the anterior two thirds of the tongue and intolerance to high-pitched or loud noises. It may cause mild dysarthria and difficulty with eating.

The most common system used for describing the degree of paralysis is the House-Brackmann scale, where 1 is normal power and 6 is total paralysis.[2]

It is important to identify whether the patient has an UMN or LMN lesion, to assist in identifying the cause.

- In an LMN lesion, the patient can't wrinkle their forehead - the final common pathway to the muscles is destroyed. The lesion must be either in the pons, or outside the brainstem (posterior fossa, bony canal, middle ear or outside skull).
- In a UMN lesion, the upper facial muscles are partially spared because of alternative pathways in the brainstem, ie the patient can wrinkle their forehead (unless there is bilateral lesion) and the sagging of the face seen with LMN palsies is not as prominent. There appear to be different pathways for voluntary and emotional movement.

Cerebrovascular accidents usually weaken voluntary movement, often sparing involuntary movements (eg, spontaneous smiling). The much rarer selective loss of emotional movement is called mimic paralysis and is usually due to a frontal or thalamic lesion.
Aetiology

LMN

- Idiopathic (Bell's palsy):
  - Pregnancy - 3x more common.
  - Diabetes mellitus.

- Cerebrovascular disease (eg, brainstem stroke).
- Iatrogenic:
  - Local anaesthetic for dental treatment.
  - Linezolid.[4]

- Infective:
  - Herpesvirus (type 1).
  - Herpes zoster (Ramsay Hunt syndrome) - see below.
  - HIV.
  - Epstein-Barr virus.
  - Cytomegalovirus.
  - Lyme disease (more likely if bilateral when responsible for 36% of cases).[5]
  - Otitis media or cholesteatoma.

- Trauma:
  - Fractures of the skull base.
  - Forceps delivery.[6]
  - Haematoma after acupuncture.[7]

- Neurological:
  - Guillain-Barré syndrome.
  - Mononeuropathy - eg, due to diabetes mellitus, sarcoidosis or amyloidosis.

- Neoplastic:
  - Posterior fossa tumours, primary and secondary.
  - Parotid gland tumours.

- Hypertension in pregnancy and eclampsia.
- Sarcoidosis.[5]
- Sjögren's syndrome and rheumatoid arthritis.[8]
- Melkersson-Rosenthal syndrome (recurrent facial palsy, chronic facial oedema of the face and lips, and hypertrophy/fissuring of the tongue).[9]

UMN

- Cerebrovascular disease.
- Intracranial tumours, primary and secondary.
- Multiple sclerosis.
- Syphilis.
- HIV.[10]
- Vasculitides.

- If bilateral, particularly consider immunosupression (HIV), Guillain-Barré syndrome or Lyme disease.
- If recurrent, particularly consider lymphoma, sarcoidosis and Lyme disease.
- In children, particularly consider Lyme disease and middle ear disease.
Characteristic features

Acute LMN palsy
Acute LMN palsy can present at any age but is most frequently seen at age 15-60 years, affecting both sexes equally. There is a rapid onset of unilateral facial paralysis:

- Ask the patient to give a big grin showing their teeth.
- Ask them to blow out their cheeks.
- Ask them to screw up their eyes.
- Ask them to raise their eyebrows (preserved in UMN lesion).
- Aching pain below the ear or in the mastoid area is also common and may suggest middle ear or herpetic cause.
- There may be hyperacusis.
- Patients with lesions proximal to the geniculate ganglion may be unable to produce tears and have loss of taste.

Bell's palsy
This, the most common cause of acute LMN facial palsy, was originally described by Sir Charles Bell in 1821.

- Incidence is 11-40 per 100,000 with a lifetime risk of 1 in 60.
- Probably caused by ischaemic compression of the facial nerve within the facial canal, as a result of inflammation, most likely due to a viral infection.
- In the past no cause was found in the majority of cases of LMN facial nerve palsy and these were labelled as idiopathic (ie Bell's palsy). Increasingly, various viral causes are being identified, particularly herpes simplex type 1 or varicella (herpes) zoster.
- Approximately 7% of patients have a recurrence.
- There may be a familial component in recurrent cases, possibly due to anatomical abnormality of the facial canal.
- The incidence is higher in people with diabetes than in those without diabetes.

Ramsay Hunt syndrome
LMN facial nerve palsy due specifically to varicella (herpes) zoster is Ramsay Hunt syndrome. Pain is often a prominent feature and vesicles are seen in the ipsilateral ear, on the hard palate and/or on the anterior two thirds of the tongue. It can include deafness and vertigo and other cranial nerves can be affected. When the rash is absent it is known as zoster sine herpete; 2-23% of people with Bell's palsy actually have Ramsay Hunt syndrome. It should be suspected when pain is significant, especially in those aged over 60. Immunodeficiency - for example, HIV - is a risk factor.

Investigations

- Serology - Lyme, herpes and zoster (paired samples 4-6 weeks apart). It may not influence management but may reveal aetiology.
- Check blood pressure in children with Bell's palsy (two case reports of aortic coarctation presenting with facial nerve palsy and hypertension).
- The following tests are rarely done but, combined with a good understanding of the neuroanatomy, can determine the level of the palsy:
  - Schirmer's tear test (reveals a reduced flow of tears on the side of a palsy affecting the greater palatine nerve).
  - Stapedial reflex (an audiological test, absent if the stapedius muscle is affected).
  - Electrodiagnostic studies (generally a research tool) reveal no changes in involved facial muscles for the first three days but a steady decline of electrical activity often occurs over the next week and will identify the 15% with axonal degeneration.

Management
Except in the mildest cases, ideally this should be a multidisciplinary approach, encompassing ophthalmologists, ENT surgeons, plastic surgeons, physiotherapists and psychologists.

General measures

- Reassurance - the majority of cases resolve spontaneously - see 'Prognosis', below.
- Eye care:
  - Ophthalmologists play an important role in preventing irreversible blindness from corneal exposure. This may be successfully achieved by using lubricating drops hourly and eye ointment at night ± an eye patch.
  - Botulinum toxin or surgery (upper lid weighting or tarsorrhaphy) may also be required temporarily. After the cornea has been protected but recovery is thought to be unlikely, longer-term management of eyelid and facial re-animation may be arranged.

Bell's palsy management
• **Steroids:**
  - Steroids are effective in the treatment of facial nerve palsy. Of the 29% that wouldn’t be expected to fully recover, a third to a half will do so if given steroids.
  - Prednisolone should be given to patients over the age of 16 presenting within 72 hours. The optimum dosing regime is not known but the following are suggested:
    - 25 mg bd for 10 days.
    - 60 mg od for 5 days then reducing by 10 mg each day.
  - There is no evidence to support the use of steroids after 72 hours.
  - It is not known whether steroids in children are effective.
  - There is moderate-quality evidence of benefit from adding antivirals to steroid therapy, with no significant increase in adverse events. This remains controversial. It is currently not recommended as treatment in the UK.
  - Physiotherapy may be beneficial but there is no high-quality evidence to support significant benefit or harm.
  - **Referral** - will depend on clinical assessment. A patient may need immediate hospital referral - eg, when there is any clinical suspicion of an underlying stroke:
    - Refer urgently to neurology or to ENT if there is:
      - Any doubt regarding the diagnosis.
      - Recurrent Bell’s palsy.
      - Bilateral Bell’s palsy.
    - If the cornea remains exposed after attempting to close the eyelid, refer urgently to ophthalmology.
    - If the paralysis shows no sign of improvement after one month, or there is suspicion of a serious underlying diagnosis (eg, cholesteatoma, parotid tumour, malignant otitis externa), refer urgently to ENT.

• **Surgery:**
  - Surgical options for patients with facial palsy not responding to medical treatment include facial nerve decompression.
  - If there is residual paralysis after 6-9 months, consider referral to a plastic surgeon with a special interest in facial reconstructive surgery. The muscle targets remain viable for cross-facial nerve grafting for about 12-18 months.
  - Where the nerve fails to regenerate, cosmetic surgery to elevate the mouth or anastomosis of the hypoglossal nerve to the facial nerve may help.

**Facial palsy in children**
- Facial palsy in children is often idiopathic but an underlying cause is increasingly being identified after thorough investigations.
- Radiological investigation is required if there is a history of trauma.
- The prognosis is variable but usually good.
Prognosis[25, 24]

- 85% improve spontaneously within three weeks of its onset.
- 71% recover fully.
- 16% have significant sequelae, 5% severe:
  - Facial asymmetry
  - Gustatory lacrimation
  - Inadequate lid closure
  - Brow ptosis
  - Drooling
  - Hemifacial spasms

Poor prognostic features:

- Complete palsy or severe degeneration (electrophysiology).
- No signs of recovery by three weeks.
- Age >60 years.
- Severe pain (suggests may be due to Ramsay Hunt syndrome).
- Ramsay Hunt syndrome (herpes zoster virus).
- Associated with either hypertension, diabetes, or pregnancy.

Those with axonal degeneration may not show any re-innervation for three months and recovery may be partial or not at all. Synkinesis is often seen - eg, blinking causes the angle of the mouth to contract. Also aberrant parasympathetic re-innervation may cause symptoms such as gustatory lacrimation ("crocodile tears"). Symptoms can be helped by subcutaneous or intramuscular injections of botulinum toxin.[25]
